Efficient Pricing of Commodity Options with Early-Exercise under the Ornstein–Uhlenbeck process

B. Zhang∗ L.A. Grzelak† C.W. Oosterlee‡

February 23, 2011

Abstract

We analyze the efficiency properties of a numerical pricing method based on Fourier-cosine expansions for early-exercise options. We focus on variants of Schwartz’ model [20] based on a mean reverting Ornstein-Uhlenbeck process [23], which is commonly used for modeling commodity prices. This process however does not possess favorable properties for the option pricing method of interest. We therefore propose an approximation of its characteristic function, so that the Fast Fourier Transform can be applied for highest efficiency.

1 Introduction

Computational Finance is one of those mathematical areas in which stochastic modeling and numerical mathematics are closely intertwined. Efficient numerical pricing methods are for example required for financial derivatives, on stocks, interest rates, credit or commodities, all governed by stochastic differential equations. In this paper we focus on a numerical pricing technique for commodity derivatives that can be exercised before the expiration date of the contract.

Movements in the commodity markets expose participants to different types of risks. An obvious way for market players to control their exposure to price and volume fluctuations is by buying or selling derivatives written on the underlying products. Bermudan but also swing options, which allow one to buy or sell extra quantities of a commodity, are commonly sold derivatives with early-exercise features.

Significant contributions have been made in modeling commodity processes by Schwartz and collaborators in [17, 20, 21] where the authors used a model

of Ornstein-Uhlenbeck type, which accounts for the mean reversion of prices, combined with a deterministic seasonality component. Often these processes are combined with independent jump components (this extension of the models studied here is straightforward). In this paper we deal with the Fourier-cosine expansion-based COS method [12, 13] for pricing early-exercise options under the stochastic processes for commodities. In this method the transitional probability density function is approximated by a Fourier-cosine series expansion, which has a direct relation to the analytically available conditional characteristic function. In [13] it was shown that the COS method can price the early-exercise and barrier options with exponential convergence under various Lévy jump models. The computational complexity for pricing a Bermudan option with \( M \) exercise dates was \( O((M - 1)N \log_2(N)) \), where \( N \) denotes the number of terms in the Fourier-cosine expansion.

In the present paper we show that this complexity cannot be easily achieved in the case of mean reverting processes of Ornstein-Uhlenbeck (OU) type. We therefore introduce an approximation of the original characteristic function, so that the COS pricing algorithm remains highly efficient for early-exercise commodity options under Ornstein-Uhlenbeck processes, but, at the same time, the error in the option prices is controlled by means of error analysis.

The paper is organized as follows. Details of the OU processes and the COS pricing method are presented in Section 2. In Section 3 the approximate OU model is introduced. It is followed by a detailed error analysis in Section 4; In Section 5 numerical results are presented. Finally conclusions are summarized in Section 6.

2 Problem Definition

2.1 The Ornstein-Uhlenbeck Process

Stochastic processes for commodities are characterized by the properties of mean reversion and seasonality. If for any reason the price of a certain commodity falls significantly due to overproduction, then market participants expect the price to rise eventually as producers decrease their supply. Moreover, incorporation of seasonality in the model is necessary since energy consumption (the use of electricity, for example) differs in different seasons of the year.

We first look at the OU process without seasonality. A commodity price can be defined as the log-transformed stochastic variable \( X_t = \log S_t \), which is then modeled by an Ornstein-Uhlenbeck mean reverting process. We define this process here under a so-called equivalent martingale measure \( Q \)

\[
\text{d}X_t = \kappa (\bar{x} - X_t) \text{d}t + \sigma \text{d}W^Q_t, \quad \text{with } X_0 = x_0,
\]

with a Brownian motion, \( W^Q_t \), is under measure \( Q \) and the parameters \( \kappa \) and \( \sigma \) represent the speed of mean reversion and volatility of the underlying process, respectively. Under this measure, the parameter \( \bar{x} := \bar{x} - \lambda \) with \( \lambda \) the market
price of risk, and \( \bar{\pi} \) the long-term mean value of the underlying process. In the derivations to follow, we will just use \( \bar{\pi} \) to denote \( \bar{\pi}^Q \).

\( X_t \) is normally distributed, i.e.:

\[
X_t \sim N\left(E(X_t), \text{Var}(X_t)\right),
\]

with:

\[
E(X_t|\mathcal{F}_0) = x_0 e^{-\kappa t} + \bar{\pi} \left(1 - e^{-\kappa t}\right),
\]

\[
\text{Var}(X_t|\mathcal{F}_0) = \frac{\sigma^2 \kappa}{2} \left(1 - e^{-2\kappa t}\right).
\]

Modeling energy prices by mean reversion is well supported by empirical studies of the price behavior, as described in [3]. General diffusion models that incorporate mean reversion go a long way in capturing the nature of energy prices; notably their tendency to randomly oscillate away from, and over time back towards, a price level determined by the cost of production. These models have gained a more wide-spread acceptance among market practitioners as progress is made in the techniques to estimate the mean reversion level and the mean reversion rates.

We are interested in the characteristic function, \( \mathbb{E}\left(e^{iuX_T|\mathcal{F}_t}\right) \), related to model (1). Based on [11] the characteristic function is of the form \( \phi(u; \tau) = e^{x_0 B(u, \tau) + A(u, \tau)} \) where \( A(u, \tau) \) and \( B(u, \tau) \) satisfy the following set of ODEs:

\[
\begin{align*}
B'(u, \tau) &= -\kappa B, \quad B(u, 0) = iu, \\
A'(u, \tau) &= \kappa x_0 B + \frac{1}{2} \sigma^2 B^2, \quad A(u, 0) = 0,
\end{align*}
\]

and the prime ‘ denotes the derivative w.r.t. \( \tau \) where \( \tau = T - t \). For the solution we find:

\[
\begin{align*}
B(u, \tau) &= iu e^{-\kappa \tau}, \\
A(u, \tau) &= \frac{1}{4\kappa} \left( e^{-2\kappa \tau} - e^{-\kappa \tau} \right) \left( u^2 \sigma^2 + u e^{\kappa \tau} (u \sigma^2 - 4i\kappa \bar{\pi}) \right).
\end{align*}
\]

Then the characteristic function of OU process reads:

\[
\phi(u; x_0) = e^{iu x_0 e^{-\kappa \tau} + A(u, \tau)}.
\]

### 2.1.1 Incorporation of Seasonality Component

More realistic stochastic processes modeling commodity prices include a seasonality component.

As presented in [7, 17] we choose a commodity price process, \( S_t \), written as:

\[
S_t = e^{g(t) + y_t} = G(t) e^{y_t}, \quad \text{with } S_0 = G(0),
\]

where \( G(t) \equiv e^{g(t)} \) is a deterministic function which describes the seasonality effect and \( y_t \) is a stochastic zero-level-mean reverting process given by:

\[
dy_t = -\kappa y_t dt + \sigma dW^y_t, \quad \text{with } y_0 = 0,
\]
with \( W_t \) a Brownian motion, \( \kappa \) corresponds to the speed of mean reversion and \( \sigma \) determines the volatility. By applying Itô’s lemma to Equation (3), and adding and subtracting \( \kappa g(t) \) and \( \sigma \), we obtain the dynamics for \( S_t \) of the form:

\[
dS_t = \left( \frac{1}{2} \sigma^2 - \kappa (y_t + g(t)) + \kappa g(t) + g'(t) \right) S_t dt + \sigma S_t dW_t^y,
\]

\( g'(t) \) being the derivative of \( g(t) \). This equals:

\[
dS_t = \left( \frac{1}{2} \sigma^2 - \kappa \log S_t + \kappa g(t) + g'(t) \right) S_t dt + \sigma S_t dW_t^y.
\]

Setting \( \theta(t) = g(t) + (\frac{1}{2} \sigma^2 + g'(t) / \kappa) \), we arrive at the following process:

\[
dS_t = \kappa (\theta(t) - \log S_t) S_t dt + \sigma S_t dW_t^y.
\]

By taking the log-transform of the stock price, \( x_t = \log S_t \), one recognizes the model to be a mean reverting Hull-White model [14], i.e.:

\[
dx_t = \kappa \left( \bar{\theta}(t) - x_t \right) dt + \sigma dW_t^y, \text{ with } x_0 = \log S_0,
\]

(4)

and \( \bar{\theta}(t) = \theta(t) - \sigma^2/2\kappa \). This model is very similar to the model in [4] for electricity prices. The OU process, \( x_t \) in (4), admits the solution:

\[
x_t = x_0 e^{-\kappa t} + \kappa \int_0^t e^{-\kappa(t-s)} \bar{\theta}(s) ds + \sigma \int_0^t e^{-\kappa(t-s)} dW_t^y,
\]

and is thus normally distributed, i.e., \( x_t \sim N(\mathbb{E}(x_t), \mathbb{V}ar(x_t)) \), with:

\[
\mathbb{E}(x_t | \mathcal{F}_0) = x_0 e^{-\kappa t} + \kappa \int_0^t e^{-\kappa(t-s)} \bar{\theta}(s) ds,
\]

\[
\mathbb{V}ar(x_t | \mathcal{F}_0) = \frac{\sigma^2}{2\kappa} \left( 1 - e^{-2\kappa t} \right).
\]

For process \( x_t = \log S_t \), as given by Equation (4), we find the following ODEs for the characteristic function:

\[
\begin{align*}
B'(u, \tau) &= -\kappa B, \quad \text{with } B(u, 0) = iu, \\
A'(u, \tau) &= \kappa \bar{\theta}(t) B(u, \tau) + \frac{1}{2} B^2(u, \tau) \sigma^2, \quad \text{with } A(u, 0) = 0.
\end{align*}
\]

So, \( B(u, \tau) = iue^{-\kappa \tau} \) and \( A(u, \tau) \) contains function \( \bar{\theta}(t) \), which is given by:

\[
\bar{\theta}(t) = \theta(t) - \frac{1}{2} \frac{\sigma^2}{\kappa} = \frac{1}{\kappa} g'(t) + g(t).
\]

The resulting ODE for \( A(u, \tau) \) admits the following solution:

\[
\begin{align*}
A(u, \tau) &= \frac{1}{2} u \int_0^\tau e^{-2\kappa s} \left[ -u \sigma^2 + 2iue^{\kappa s} (\kappa g(s) + \partial_s g(s)) \right] ds, \\
&= \frac{1}{4} u^2 \sigma^2 \left( e^{-2\kappa \tau} - 1 \right) + iu \int_0^\tau e^{-\kappa s} \left( \kappa g(s) + \partial_s g(s) \right) ds.
\end{align*}
\]
2.2 The Fourier-Cosine Method (COS)

The Fourier-cosine pricing method, COS [12, 13], is based on the risk-neutral option valuation formula (discounted expected payoff approach):

\[ v(x, t_0) = e^{-r \Delta t} \int_{-\infty}^{\infty} v(y, T) f(y|x) \, dy, \]

where \( v(x, t_0) \) is the present option value, \( r \) the interest rate, \( \Delta t = T - t_0 \) and \( x, y \) can be any monotone functions of the underlying asset at initial time \( t_0 \) and the expiration date \( T \), respectively. Function \( v(y, T) \), which for European option equals the payoff, is known, but the transitional density function, \( f(y|x) \), typically is not. Based on Equation (5), we approximate the conditional density function on a truncated domain, by a truncated Fourier-cosine expansion, which recovers the conditional density function from its characteristic function (see [12]) as follows:

\[ f(y|x) \approx \frac{2}{b-a} \sum_{k=0}^{N-1} \text{Re} \left( \phi\left( \frac{k\pi}{b-a}; x \right) \exp \left( -i \frac{ak\pi}{b-a} \right) \cos \left( k\pi \frac{y-a}{b-a} \right) \right), \]

with \( \phi(u; x) \) the characteristic function of \( f(y|x) \), \( a, b \) determine the truncation interval and \( \text{Re} \) means taking the real part of the argument. The prime at the sum symbol indicates that the first term in the expansion is multiplied by one-half. The appropriate size of the integration interval can be determined with the help of the cumulants [12] \(^1\).

Replacing \( f(y|x) \) by its approximation (6) in Equation (5) and interchanging integration and summation gives the COS formula for computing the values of European options:

\[ v(x, t_0) = e^{-r\tau} \sum_{k=0}^{N-1} \text{Re} \left( \phi\left( \frac{k\pi}{b-a}; x \right) e^{-ik\pi \frac{a}{b-a}} \right) V_k, \]

where \( \tau = T - t \) stands for time to maturity, and

\[ V_k = \frac{2}{b-a} \int_a^b v(y, T) \cos \left( k\pi \frac{y-a}{b-a} \right) \, dy, \]

are the Fourier-cosine coefficients of \( v(y, T) \), available in closed form for several payoff functions.

It was found that, with integration interval \([a, b]\) chosen sufficiently wide, the series truncation error dominates the overall error. For conditional density functions \( f(y|x) \in C^\infty((a, b) \subset \mathbb{R}) \), the method converges exponentially; otherwise convergence is algebraically [13].

Formula (7) also forms the basis for the pricing of Bermudan options [13].

\(^1\)So that \( \int_a^b f(y|x) \, dy - \int_a^b f(y|x) \, dy < TOL. \)
2.2.1 Pricing Bermudan Options

A Bermudan option can be exercised at pre-specified dates before maturity. The holder receives the exercise payoff when he/she exercises the option. Let \( t_0 \) denote the initial time and \( \{ t_1, \cdots, t_M \} \) be the collection of all exercise dates with \( \Delta t := (t_m - t_{m-1}), \) \( t_0 < t_1 < \cdots < t_M = T \). The pricing formula for a Bermudan option with \( M \) exercise dates then reads, for \( m = M, M-1, \ldots, 2 \):

\[
\begin{align*}
    c(x, t_{m-1}) &= e^{-r \Delta t} \int_{\mathbb{R}} v(y, t_m) f(y|x) dy, \\
v(x, t_{m-1}) &= \max \left( g(x, t_{m-1}), c(x, t_{m-1}) \right),
\end{align*}
\]

followed by

\[
v(x, t_0) = e^{-r \Delta t} \int_{\mathbb{R}} v(y, t_1) f(y|x) dy.
\]

Here \( x \) and \( y \) are state variables, here defined as 

\[
x := \ln(S(t_{m-1})) \quad \text{and} \quad y := \ln(S(t_m)),
\]

\( v(x, t), c(x, t) \) and \( g(x, t) \) are the option value, the continuation value and the payoff at time \( t \), respectively. For call and put options, \( g(x, t) \equiv v(x, T) \), with

\[
v(x, T) = \max \left[ \alpha (e^x - K), 0 \right], \quad \alpha = \begin{cases} 1 & \text{for a call,} \\ -1 & \text{for a put.} \end{cases}
\]

The idea of pricing Bermudan options by the COS method is to first determine the Fourier-cosine coefficients of the option value at \( t_1, V_k(t_1) \), and then insert them into (9). The derivation of an induction formula for \( V_k(t_1) \) was the basis of the work in [13]. It is briefly explained here. The continuation value in (8) can be defined by means of the COS formula for different underlying processes:

\[
c(x, t_{m-1}) := e^{-r \Delta t} \sum_{k=0}^{N-1} \text{Re} \left\{ \phi \left( \frac{k\pi}{b-a}; x \right) e^{-ik\pi \frac{x-a}{b-a}} \right\} V_k(t_m).
\]

Here the function \( c(x, t_{m-1}) \) represents the approximation of the continuation value.

First, the early-exercise point, \( x_m^* \), at time \( t_m \), which is the point where the continuation value equals the payoff, i.e., \( c(x_m^*, t_m) = g(x_m^*, t_m) \), is determined for example by Newton’s method.

Based on \( x_m^* \), we can split \( V_k(t_m) \) into two parts: One on the interval \( [a, x_m^*] \) and the other on \( (x_m^*, b] \), i.e.

\[
V_k(t_m) = \begin{cases} C_k(a, x_m^*, t_m) + G_k(x_m^*, b), & \text{for a call,} \\ G_k(a, x_m^*) + C_k(x_m^*, b, t_m), & \text{for a put,} \end{cases}
\]

for \( m = M - 1, M - 2, \cdots, 1 \), and

\[
V_k(t_M) = \begin{cases} G_k(0, b), & \text{for a call} \\ G_k(a, 0), & \text{for a put,} \end{cases}
\]
whereby
\[ G_k(x_1, x_2) := \frac{2}{b - a} \int_{x_1}^{x_2} g(x, t_m) \cos \left( k\pi \frac{x - a}{b - a} \right) dx. \] (14)

and
\[ C_k(x_1, x_2, t_m) := \frac{2}{b - a} \int_{x_1}^{x_2} c(x, t_m) \cos \left( k\pi \frac{x - a}{b - a} \right) dx. \] (15)

For \( k = 0, 1, \cdots, N - 1 \) and \( m = 1, 2, \cdots, M \), \( G_k(x_1, x_2) \) in (14) admits analytic solutions.

The properties a characteristic function should satisfy for the efficient computation of the \( C_k(x_1, x_2, t_m) \)-coefficients (15) can be found from the following definition and lemma.

**Definition 2.1.** We write the characteristic function between two consecutive time points as:
\[ \phi(u; x) = e^{iux} \phi_A(u, \Delta t), \] (16)
where \( \phi_A(u, \Delta t) \) does not contain \( x \).

By (16), we distinguish two types of stochastic processes based on their characteristic functions. In the first type \( \beta = 1 \), which contains the exponential Lévy processes, for which the characteristic function can be written in the form \( \phi(u; x) = e^{iux} \phi_A(u, \Delta t) \). Examples for these processes are Geometric Brownian Motion, jump-diffusion processes of Kou [15] or Merton [19], or infinite activity Lévy processes [9], like Variance-Gamma (VG) [18], Normal Inverse Gaussian (NIG) [1] or CGMY [5].

For the second type of processes, \( \phi(u; x) \) cannot be written as a product of \( e^{iux} \) and a function which does not contain \( x \). A first example is the OU mean reverting process, where \( \beta = e^{-\kappa \Delta t} \) and \( \phi_A(u, \Delta t) = \exp(A(u, \Delta t)) \) with \( A(u, \Delta t) \) defined in (2).

In the lemma to follow we will see that a process with a characteristic function of the first type is beneficial for pricing Bermudan options by the COS method as the Fast Fourier Transform can be applied.

**Lemma 2.1** (Efficient Computation). The terms \( C_k(x_1, x_2, t_m) \) can be computed in \( O(N \log_2 N) \) operations, if the stochastic process for the underlying is governed by the general characteristic function (16) with parameter \( \beta = 1 \).

Proof. At time \( t_m \), \( m = 1, 2, \cdots, M \), from Equations (7) and (8) we obtain an approximation for \( c(x, t_m) \), the continuation value at \( t_m \), which is inserted into (15). Interchanging summation and integration gives the following coefficients, \( C_k(x_1, x_2, t_m) \):
\[ C_k(x_1, x_2, t_m) := e^{-r \Delta t} \sum_{j=0}^{N-1} Re\left( \phi_A \left( \frac{j\pi}{b - a}, \Delta t \right) V_j(t_{m+1}) \cdot H_{k,j}(x_1, x_2) \right), \] (17)
where $\phi_A(u, \tau)$ comes from the general expression for the characteristic function (16). To get $C_k(x_1, x_2, t_m)$, the following integrals need to be computed:

$$H_{k,j}(x_1, x_2) = \frac{2}{b - a} \int_{x_1}^{x_2} e^{ij\beta x} \frac{x - a}{b - a} \cos(k\pi \frac{x - a}{b - a}) dx,$$

with $\beta$ defined in (16).

From basic calculus, we can split $H_{k,j}(x_1, x_2)$ into two parts as

$$H_{k,j}(x_1, x_2) = -\frac{i}{\pi}(H^c_{k,j}(x_1, x_2) + H^s_{k,j}(x_1, x_2)),$$

where

$$H^c_{k,j}(x_1, x_2) = \begin{cases} \frac{(x_2 - x_1)\pi i}{(j\beta + k)} & \text{if } k = j = 0, \\ \frac{1}{(j\beta + k)} \left[ \exp \left( \frac{(j\beta + k)x_2 - (j + k)a\pi i}{b - a} \right) \right] - \\ \exp \left( \frac{(j\beta + k)x_2 - (j + k)a\pi i}{b - a} \right), & \text{otherwise.} \end{cases}$$

and

$$H^s_{k,j}(x_1, x_2) = \begin{cases} \frac{(x_2 - x_1)\pi i}{(j\beta - k)} & \text{if } k = j = 0, \\ \frac{1}{(j\beta - k)} \left[ \exp \left( \frac{(j\beta - k)x_2 - (j - k)a\pi i}{b - a} \right) \right] - \\ \exp \left( \frac{(j\beta - k)x_2 - (j - k)a\pi i}{b - a} \right), & \text{otherwise.} \end{cases}$$

Then to determine the value of $C_k(x_1, x_2, t_m)$, we have to compute:

$$C_k(x_1, x_2, t_m) = -\frac{i e^{-r\Delta t}}{\pi} \sum_{j=0}^{N-1} \text{Re}(\phi_A(\frac{j\pi}{b - a}, V_j(t_{m+1}))) \cdot$$

$$\left( H^c_{k,j}(x_1, x_2) + H^s_{k,j}(x_1, x_2) \right),$$

(20)

(21)

Matrices $H_s := \{H^s_{k,j}(x_1, x_2)\}_{k,j=0}^{N-1}$ and $H_c := \{H^c_{k,j}(x_1, x_2)\}_{k,j=0}^{N-1}$ have a Toeplitz or Hankel structure, respectively, if and only if for all $k,j,x_1,x_2$, $H^s_{k,j}(x_1, x_2) = H^s_{k+1,j+1}(x_1, x_2)$, and $H^c_{k,j}(x_1, x_2) = H^c_{k+1,j-1}(x_1, x_2)$, which is for $\beta = 1$. Then, the Fast Fourier Transform can be applied directly for highly efficient matrix-vector multiplication [13], and the resulting computational complexity for $C_k(x_1, x_2, t_m)$ is $O(N \log_2 N)$.

We obtain however terms of the form $j\beta - k, j\beta + k$ in the matrix elements in (18) and (19), where $\beta = e^{-\kappa \Delta t}$ for the OU process, instead of terms with $j - k, j + k$, for the Lévy jump processes in [13]. Terms with $\beta$ not being an integer hamper an efficient computation of the matrix-vector products, leading to computations of $O(N^2)$ complexity. In the next section we will therefore introduce an approximate OU model so that the efficient pricing technique with FFT can be applied.
3 An Approximate OU Model

In this section we introduce an approximation for the characteristic function of the OU processes from Section 2, so that the performance of the COS method for Bermudan options should improve in terms of computational complexity. The aim is to make use of the FFT algorithm as much as possible with the modified characteristic function. Without loss of generality, we will focus on Bermudan put options here.

The original characteristic functions of the OU processes with and without seasonality can be written as:

$$\phi_{ou}(u, x) = e^{iux} e^{A(u, \Delta t) - iux(1 - e^{-\kappa \Delta t})} =: e^{iux} \overline{\phi}(u, x).$$  \hspace{1cm} (22)

Here $\overline{\phi}(u, x) = \phi_A(u, \Delta t)e^{-iux(1 - e^{-\kappa \Delta t})}$ with $\phi_A(u, \Delta t)$ defined in (16). Without seasonality we have:

$$A(u, \Delta t) = \frac{1}{4\kappa} (e^{-2\kappa \Delta t} - e^{-\kappa \Delta t})(u^2 \sigma^2 + ue^{\kappa \Delta t}(u\sigma^2 - 4i\kappa x)),$$

and with seasonality:

$$A(u, \Delta t) = \frac{1}{4\kappa} u^2 \sigma^2 (e^{-2\kappa \Delta t} - 1) + iu \int_t^T e^{-\kappa(T-s)}(\kappa g(s) + \frac{\partial}{\partial s} g(s))ds.$$

We approximate $\phi(u, x)$ in (22) by another function, which does not contain $x$. The characteristic function is then of the form (16) with $\beta = 1$, so that the Fast Fourier Transform can be used in the computation of $C_k(x_1, x_2, t_m)$. At each time step, $t_m$, function $\overline{\phi}(u, x_{t_m})$ is here approximated by

$$\overline{\phi}(u, x_{t_m}) \approx \overline{\phi}(u, E(x_{t_m}|F_0)).$$  \hspace{1cm} (23)

The approximate characteristic function, denoted by $\phi_{app}$, then reads:

$$\phi_{app}(u, x) = e^{iux} \overline{\phi}(u, E(x|F_0)).$$  \hspace{1cm} (24)

This approximation may not be accurate for all model parameters when pricing Bermudan options. Comparison of the original characteristic function (22) with this approximation (24) gives us that

$$\phi_{app}(u, x) = \phi_{ou}(u, x)e^{i\epsilon_1},$$  \hspace{1cm} (25)

where $\epsilon_1$ reads

$$\epsilon_1 = (x - E(x))(1 - e^{-\kappa \Delta t}).$$  \hspace{1cm} (26)

Based on (25) the approximation proposed may only be considered accurate for sets of model parameters for which $\epsilon_1$ in (26) is less than a prescribed tolerance level. This tolerance level is defined so that the Bermudan option prices resulting from the approximate characteristic function at each time step are accurate up to a basis point compared to the option prices obtained by the original characteristic function of the OU process.

The tolerance level for $\epsilon_1$, as well as the requirements model parameters should satisfy so that the approximate characteristic function (24) is accurate and thus the Fast Fourier Transform can be used at each time step, are determined by an error analysis in the next section.
4 Error analysis

Our aim is to keep the error, defined as the difference between Bermudan option values calculated with the original characteristic function and those obtained with \( x_t \) approximated by \( E(x_t) \) in (22), less than a basis point, which is 1/100-th of a percentage point. Here we discuss how the error in the option value can be controlled and the basis point precision can be achieved.

We first introduce the following notation:

- \( \hat{\epsilon}_c(x, t) \) is the error in the continuation value \( c(x, t) \) at time \( t \).
- \( \epsilon_x(t) \) is the error in early–exercise point \( x^* \) at time \( t \).
- \( \epsilon_V(t) \) is the error in \( V_k \) at time \( t \), i.e. the error in the Fourier-cosine coefficients of option value \( v(x, t) \).

We focus here on the error in Bermudan option values resulting from our approximate characteristic function. For convergence analysis of the COS pricing method we refer the reader to [12] and [13].

4.1 The first step in the backward recursion

The first step in the backward recursion is from \( t_M \equiv T \) to \( t_{M-1} \). The error in the characteristic function, due to the approximation, gives an error in the continuation value, \( c(x, t_{M-1}) \), as well as a shift in the early-exercise point, \( x^*_{t_{M-1}} \). These errors contribute to \( \epsilon_V(t_{M-1}) \), the error in \( V_k(t_{M-1}) \).

The connection between the error in the continuation value and the error in the characteristic function is presented in the following lemma.

**Lemma 4.1.** The error in continuation value reads

\[
\hat{\epsilon}_c(x, t_{M-1}) = c(x + e^{\kappa \Delta t} \epsilon_1, t_{M-1}) - c(x, t_{M-1}),
\]

with \( \epsilon_1 \) defined in (26).

**Proof.** Applying (22) and (25) gives us:

\[
\phi_{app}(u, x) = \exp(iu xe^{-\kappa \Delta t} + A(u) + iue^{-\kappa \Delta t}(e^{\kappa \Delta t} \epsilon_1)) \\
= \exp(iu(x + e^{\kappa \Delta t} \epsilon_1)e^{-\kappa \Delta t} + A(u)) \\
= \phi_{ou}(u, x + e^{\kappa \Delta t} \epsilon_1). \tag{28}
\]

By substituting (28) in the COS pricing formula (7), we obtain:

\[
\hat{c}(x, t_{M-1}) = c(x + e^{\kappa \Delta t} \epsilon_1, t_{M-1}),
\]

which results in:

\[
\hat{\epsilon}_c(x, t_{M-1}) = c(x + e^{\kappa \Delta t} \epsilon_1, t_{M-1}) - c(x, t_{M-1}).
\]

\qed
Then we have the next corollary.

**Corollary 4.1.** For put options, if $\epsilon_1 > 0$, then $\epsilon_c(x, t_{M-1}) < 0 \ \forall x$, and subsequently $\epsilon_x(t_{M-1}) > 0$, and vice versa if $\epsilon_1 < 0$.

**Proof.** The continuation value, $c(x, t)$, is a decreasing function for put options. This implies that, for $\epsilon_1 > 0$,

$$
\epsilon_c(x, t_{M-1}) := c(x + e^{\kappa \Delta t} \epsilon_1, t_{M-1}) - c(x, t_{M-1}) < 0.
$$

In this case, we have that at the early-exercise point related to the original characteristic function, $x^*_{t_{M-1}}$:

$$
\hat{c}(x^*_{t_{M-1}}, t_{M-1}) < c(x^*_{t_{M-1}}, t_{M-1}) = g(x^*_{t_{M-1}}, t_{M-1}).
$$

So, the continuation value is smaller than the payoff. Therefore, the approximate early-exercise point is larger than the original $x^*_{t_{M-1}}$ and thus $\epsilon_x(t_{M-1}) > 0$.

For $\epsilon_1 < 0, \forall x$, the proof that for $\epsilon_c(x, t_{M-1}) > 0 \ \forall x$, and that $\epsilon_x(t_{M-1}) < 0$ goes similarly. \hfill \Box

The upper bounds of $|\epsilon_c(x, t_{M-1})|$ and $|\epsilon_x(t_{M-1})|$ are found in the next lemma.

**Lemma 4.2.** $\forall x$ in the range of integration $[a, b], \ \forall t$, we have that

$$
|c(x + e^{\kappa \Delta t} \epsilon_1, t) - c(x, t)| \leq e^{\kappa \Delta t} |\epsilon_1| =: \hat{\epsilon}_c,
$$

which implies:

$$
|\epsilon_c(x, t_{M-1})| \leq \hat{\epsilon}_c, \ \forall x \in [a, b].
$$

Error $|\epsilon_x(t_{M-1})|$ can furthermore be bounded in terms of $\hat{\epsilon}_c$.

**Proof.** Application of Lagrange’s mean value theorem, gives

$$
\left| c(x + e^{\kappa \Delta t} \epsilon_1, t) - c(x, t) \right| = e^{\kappa \Delta t} \left| \frac{\partial c(x, t)}{\partial x} x = \delta_0 \right| \left| \epsilon_1 \right|,
$$

where $\delta_0 \in (x, x + e^{\kappa \Delta t} \epsilon_1)$. The function $\partial c(x, t) / \partial x$ is a non-positive and non-decreasing\(^2\) function in $x$ for Bermudan put options, which goes to zero as $x \to \infty$. Therefore, we have

$$
\max_{x \in [a, b]} \left| \frac{\partial c(x, t)}{\partial x} \right| = \left| \frac{\partial c(x, t)}{\partial x} \right|_{x=a}.
$$

We denote this derivative of the continuation value at $a$ by $c'(a, t)$, and:

$$
|c(x + e^{\kappa \Delta t} \epsilon_1, t) - c(x, t)| \leq e^{\kappa \Delta t} |\epsilon_1| |c'(a, t)|.
$$

\(^2\)It is non-decreasing is because the payoff of a put option is convex, which implies that the gamma, $\partial^2 c(x, t)/\partial x^2$, is non-negative indicating a non-decreasing first derivative $\partial c(x, t)/\partial x$. This holds for a long position in the option.
At each time step we have that $|c'(x,t)| \leq |g'(x,t)|$ for $x \leq x^* \leq \log(K)$, $(x^*$ being the early-exercise point related to the original OU process which should not exceed $\log(K)$ for a put option on a log-scale). So, if $x^* > a$, $|c'(a,t)| \leq |g'(a,t)| \leq e^a$. The second inequality follows from $|g'(x,t)| \leq e^x$, as $g'(x,t) = -e^x$ for $x \leq \log(K)$ and $g'(x,t) = 0$ otherwise for a put option. For deep out–of–the money options for which $x^* \leq a$, we find

$$|c'(a,t)| \leq |c'(x^*,t)| \leq |g'(x^*,t)| \leq e^{x^*} \leq e^a. \quad (34)$$

Summarizing, we find for all cases:

$$|c'(a,t)| \leq e^a. \quad (35)$$

Substitution of (35) in (33) gives us that for $\forall x \in [a,b]$ and for $\forall t$,

$$|c(x + e^\kappa \Delta t \epsilon_1, t) - c(x, t)| \leq e^a e^\kappa \Delta t |\epsilon_1| =: \epsilon_c,$$

which implies $|e_c(x,t_{M-1})| \leq \epsilon_c$. Now we look at the error in the early–exercise point at $t_{M-1}$. Assume points $x_{t_{M-1}}^*$ and $x_{t_{M-1}}^* + \epsilon_x(t_{M-1})$ are the early–exercise points obtained from the original and the approximate characteristic functions, respectively. It follows that

$$c(x_{t_{M-1}}^*, t_{M-1}) = g(x_{t_{M-1}}^*, t_{M-1}),$$
$$\hat{c}(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) = g(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}).$$

Therefore

$$g(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) - c(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1})$$
$$= \hat{c}(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) - c(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1})$$
$$=: \epsilon_c(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}).$$

We introduce a new function $f(x,t) := g(x,t) - c(x,t)$, so that we have

$$f(x_{t_{M-1}}^*, t_{M-1}) = 0,$$
$$f(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) = \epsilon_c(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}).$$

Application of (30) gives:

$$|f(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) - f(x_{t_{M-1}}^*, t_{M-1})| = |\epsilon_c(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1})| \leq \epsilon_c. \quad (36)$$

Using Lagrange’s mean value theorem for (36) gives us

$$|\epsilon_x(t_{M-1})||f'(\tilde{\delta}, t_{M-1})| \leq \epsilon_c,$$

for some $\tilde{\delta} \in (x_{t_{M-1}}^*, x_{t_{M-1}}^* + \epsilon_x(t_{M-1})).$

The fact that there is one early–exercise point for plain Bermudan put options implies that

$$|f(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) - f(x_{t_{M-1}}^*, t_{M-1})| > 0.$$
If there is an error in the early–exercise point, i.e., if \( \epsilon_x(t_{M-1}) \neq 0 \), we have that \(|f'(\delta, t_{M-1})| > 0\), so that

\[
|\epsilon_x(t_{M-1})| \leq \frac{\epsilon_c}{|f'(\delta, t_{M-1})|}
\]  

(37)

Hence \(|\epsilon_x(t_{M-1})|\) is bounded in terms of \(\epsilon_c\). If \(\epsilon_c\) tends to zero, then \(|\epsilon_x(t_{M-1})|\) also tends to zero.

At the other time points, \(m = 0, \ldots, M - 2\), the upper bound for the shift in the early–exercise point can also be determined in terms of the error in the continuation value. However, unlike time step \(t_{M-1}\), the error in the continuation value is not only related to the approximate characteristic function, but also to the error in \(V_k(t)\),

\[
V_k(t) := \int_a^b \max(c(x,t), g(x,t)) \cos(k\pi \frac{x-a}{b-a}) dx.
\]

We first have a look at the error in \(V_k(t_{M-1})\) from (12) in the following lemma. We will need the results in the lemma to derive upper bounds in the lemmas to follow.

**Lemma 4.3.** For \(\epsilon_x(t_{M-1}) > 0\), two points, \(\delta_1 \in (x^*_t, t_{M-1} + \epsilon_x(t_{M-1}), b)\) and \(\delta_2 \in (x^*_t, t_{M-1} + \epsilon_x(t_{M-1}), a)\) exist, so that

\[
\epsilon_V(t_{M-1}) = \epsilon_c(\delta_1, t_{M-1}) I_k(x^*_t, \epsilon_x(t_{M-1}), b) + (g(\delta_2, t_{M-1}) - c(\delta_2, t_{M-1})) I_k(x^*_t, t_{M-1} + \epsilon_x(t_{M-1}))
\]  

(38)

where

\[
I_k(x_1, x_2) = \frac{2}{b-a} \int_{x_1}^{x_2} \cos(k\pi \frac{x-a}{b-a}) dx,
\]

(39)

can be viewed as the (analytically available) Fourier-cosine coefficient of an option with value:

\[
v_I(x, x_1, x_2) = \begin{cases} 1 & \text{if } x \in [x_1, x_2], \\ 0 & \text{otherwise}. \end{cases}
\]

(40)

Moreover, we have that \(|\epsilon_c(\delta_1, t_{M-1})| \leq \epsilon_c\), and

\[
|g(\delta_2, t_{M-1}) - c(\delta_2, t_{M-1})| \leq \epsilon_c.
\]

(41)

**Proof.** Here we assume that both early–exercise points, for the original and approximate OU processes, lie in the integration range. If either \(x^*_t\) or \(x^*_t + \epsilon_x\) lies outside range \([a, b]\), it is set equal to the nearest boundary point. \(V_k\) can thus be split as in (12) depending on the early–exercise point.

Let us first analyze the case of a positive error, \(\epsilon_x(t_{M-1})\), in the early–exercise point at \(t_{M-1}\). Between \(x^*_t + \epsilon_x(t_{M-1})\) and \(b\), for the original and the approximate OU processes, we use the continuation value. The error in
$V_k(t_{M-1})$ in this interval originates from the error in the continuation value, $\epsilon_c(x, t_{M-1})$. This error, which is denoted by $\epsilon V_1(t_{M-1})$, reads:

$$\epsilon V_1(t_{M-1}) = \frac{2}{b - a} \int_{x_{t_{M-1}}^* + \epsilon_x(t_{M-1})}^{b} \epsilon_c(x, t_{M-1}) \cos(k\pi \frac{x - a}{b - a}) dx.$$ 

By application of the first mean value theorem for integration, there exists a $\delta_1 \in (x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), b)$, so that

$$\epsilon V_1(t_{M-1}) = \frac{2\epsilon_c(\delta_1, t_{M-1})}{b - a} \int_{x_{t_{M-1}}^* + \epsilon_x(t_{M-1})}^{b} \cos(k\pi \frac{x - a}{b - a}) dx$$

$$= \epsilon_c(\delta_1, t_{M-1}) I_k(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), b),$$  \hspace{0.5cm} (42)

with $I_k$ from (39). From (30) we have that $|\epsilon_c(\delta_1, t_{M-1})| \leq \hat{\epsilon}_c$.

Between $a$ and $x_{t_{M-1}}^*$, for both the original and approximate OU processes, we take the payoff function which for a put option reads $g(x, t) = \max(K - e^x, 0)$. There is no error in the payoff function, hence no error in $V_k(t_{M-1})$ along this part of the x-axis.

Between $x_{t_{M-1}}^*$ and $x_{t_{M-1}}^* + \epsilon_x(t_{M-1})$, with the original OU process we use continuation value, $c(x, t_{M-1})$. However, due to the shift in the early—exercise point we have the payoff $g(x, t_{M-1})$ instead when using the approximate OU process. This leads to an error in $V_k(t_{M-1})$, denoted by $\epsilon V_2(t_{M-1})$, which reads:

$$\epsilon V_2(t_{M-1}) = \frac{2}{b - a} \int_{x_{t_{M-1}}^* + \epsilon_x(t_{M-1})}^{x_{t_{M-1}}^*} (g(x, t_{M-1}) - c(x, t_{M-1})) \cos(k\pi \frac{x - a}{b - a}) dx.$$ 

By application again of the first mean value theorem for integration, there exists a $\delta_2 \in (x_{t_{M-1}}^*, x_{t_{M-1}}^* + \epsilon_x(t_{M-1}))$, so that

$$\epsilon V_2(t_{M-1}) = (g(\delta_2, t_{M-1}) - c(\delta_2, t_{M-1})) \cdot \frac{2}{b - a} \int_{x_{t_{M-1}}^*}^{x_{t_{M-1}}^* + \epsilon_x(t_{M-1})} \cos(k\pi \frac{x - a}{b - a}) dx$$

$$= (g(\delta_2, t_{M-1}) - c(\delta_2, t_{M-1})) I_k(x_{t_{M-1}}^*, x_{t_{M-1}}^* + \epsilon_x(t_{M-1})).$$ \hspace{0.5cm} (43)

For a put option, \forall $t$, for all $x > x_t^*$, $c(x, t) - g(x, t) > 0$, and function $c(x, t) - g(x, t)$ is non—decreasing \footnote{For put options in log-scale when $x \leq 0$, function $c(x, t) - g(x, t)$ is non—decreasing and for $x \geq 0$, $c(x, t) - g(x, t)$ is non—increasing. For a put option early—exercise points are negative. Therefore, between the two early—exercise points, $x_t^*$ and $x_t^* + \epsilon_x(t)$, $c(x, t) - g(x, t)$ is non—decreasing.} between $x_t^*$ and $x_t^* + \epsilon_x(t)$. This implies:

$$|g(\delta_2, t_{M-1}) - c(\delta_2, t_{M-1})| = c(x_{t_{M-1}}^* + \epsilon_x(t_{M-1}), t_{M-1}) - g(x_{t_{M-1}}^*, t_{M-1}) \leq |\epsilon_c(\delta_2, t_{M-1}) - \epsilon_x(t_{M-1})| \leq \hat{\epsilon}_c.$$ 

The last step is from (30).
Adding up (42) and (43) gives
\[
\epsilon_V(t_{M-1}) = \epsilon_V(t_{M-1}) + \epsilon_V(t_{M-1})
\]
\[
= \epsilon_c(\delta_1, t_{M-1})I_k(x^*_{t_{M-1}}, \epsilon_x(t_{M-1}), b) + \\
(\hat{g}(\delta_2, t_{M-1}) - g(\delta_2, t_{M-1}))I_k(x^*_{t_{M-1}}, \epsilon_x(t_{M-1}))
\]

\[\square\]

**Remark 4.1.** The case when \(\epsilon_x(t_{M-1}) < 0\) goes similarly. It can then be proved that points \(\delta_1 \in (x^*_{t_{M-1}}, b)\) and \(\delta_2 \in (x^*_{t_{M-1}}, \epsilon_x(t_{M-1}), x^*_{t_{M-1}})\) exist, so that
\[
\epsilon_V(t_{M-1}) = \epsilon_c(\delta_1, t_{M-1})I_k(x^*_{t_{M-1}}, b) + \\
(\hat{c}(\delta_2, t_{M-1}) - g(\delta_2, t_{M-1}))I_k(x^*_{t_{M-1}}, \epsilon_x(t_{M-1}))
\]

Moreover, \(|\epsilon_c(\delta_1, t_{M-1})| \leq \hat{\epsilon}_c\), and \(|\hat{c}(\delta_2, t_{M-1}) - g(\delta_2, t_{M-1})| \leq \hat{\epsilon}_c\).

### 4.2 Steps in the backward recursion

We analyze the case \(t = t_{M-2}\) in the following lemma.

**Lemma 4.4.** For \(\forall x \in [a, b]\), \(|\epsilon_c(x, t_{M-2})| \leq \hat{\epsilon}_c(1 + e^{-r\Delta t})\).

**Proof.** At \(t = t_{M-2}\) we have
\[
|\epsilon_c(x, t_{M-2})| := |\hat{c}(x, t_{M-2}) - c(x, t_{M-2})|
\]
\[
= |e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{app}(\frac{k\pi}{b-a}; x) e^{-ik\pi \frac{a}{b-a}})(V_k(t_{M-1}) + \epsilon_V(t_{M-1}))
\]
\[
- e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{ou}(\frac{k\pi}{b-a}; x) e^{-ik\pi \frac{a}{b-a}})V_k(t_{M-1})| (45)
\]

Application of (28) gives:
\[
|\epsilon_c(x, t_{M-2})| \leq |e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{app}(\frac{k\pi}{b-a}; x) e^{-ik\pi \frac{a}{b-a}})\epsilon_V(t_{M-1})|
\]
\[
+ |e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{ou}(\frac{k\pi}{b-a}; x + e^{\kappa\Delta t} \epsilon_1) e^{-ik\pi \frac{a}{b-a}}) V_k(t_{M-1})|
\]
\[
- e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{ou}(\frac{k\pi}{b-a}; x) e^{-ik\pi \frac{a}{b-a}}) V_k(t_{M-1})|
\]
\[
\leq |e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{app}(\frac{k\pi}{b-a}; x) e^{-ik\pi \frac{a}{b-a}})\epsilon_V(t_{M-1})| + \hat{\epsilon}_c. (46)
\]

The last step is from (29).
By application of Lemma 4.3, Equation (41) we have that, for \( \epsilon_x(t_{M-1}) > 0 \),
\[
|e^{-\Delta t} \sum_{k=0}^{N-1} \text{Re}(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi \frac{x}{b-a}}) \epsilon_V(t_{M-1})| \leq |\epsilon_c(\delta_1, t_{M-1})| \cdot |e^{-\Delta t} \sum_{k=0}^{N-1} \text{Re}(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi \frac{x}{b-a}}) I_k(x^*_{t_{M-1}} + \epsilon_x(t_{M-1}), b)| + |\epsilon_c(\delta_2, t_{M-1}) - \epsilon_c(\delta_1, t_{M-1})| \cdot |e^{-\Delta t} \sum_{k=0}^{N-1} \text{Re}(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi \frac{x}{b-a}}) I_k(x^*_{t_{M-1}} + \epsilon_x(t_{M-1}), b)|.
\]
Substitution of (48) in (47) gives us
\[
|e^{-\Delta t} \sum_{k=0}^{N-1} \text{Re}(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi \frac{x}{b-a}}) \epsilon_V(t_{M-1})| \leq \hat{\epsilon}_c e^{-\Delta t} \epsilon_x(t_{M-1}) | x^*_{t_{M-1}}, b) \),
\]
where we have used the fact that option values, represented by the cosine series with \( I_k(\cdot, \cdot) \), are positive. From (40) we have
\[
v_I(x + e^{N-\Delta t} \epsilon_1, x^*_{t_{M-1}}, b) = e^{-\Delta t} \int f(y|x + e^{N-\Delta t} \epsilon_1) dy \leq e^{-\Delta t} \int f(y|x + e^{N-\Delta t} \epsilon_1) dy = e^{-\Delta t}. \quad (48)
\]
Substitution of (48) in (47) gives us
\[
|e^{-\Delta t} \sum_{k=0}^{N-1} \text{Re}(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi \frac{x}{b-a}}) \epsilon_V(t_{M-1})| \leq \hat{\epsilon}_c e^{-\Delta t} \quad (49)
\]
By using (49) in (46), we obtain
\[
|\epsilon_c(x, t_{M-2})| \leq \hat{\epsilon}_c + \hat{\epsilon}_c e^{-\Delta t} = \hat{\epsilon}_c(1 + e^{-\Delta t}).
\]
When \( \epsilon_x(t_{M-1}) < 0 \) it follows similarly, from (46) and Remark 4.1, that
\[
|\epsilon_c(x, t_{M-2})| \leq \hat{\epsilon}_c + |e^{-\Delta t} \sum_{k=0}^{N-1} \text{Re}(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi \frac{x}{b-a}}) \epsilon_V(t_{M-1})| \leq \hat{\epsilon}_c + |\epsilon_c(\delta_1, t_{M-1})| \cdot |v_I(x + e^{N-\Delta t} \epsilon_1, x^*_{t_{M-1}}, b)| + |\epsilon_c(\delta_2, t_{M-1}) - \epsilon_c(\delta_1, t_{M-1})| \cdot |v_I(x + e^{N-\Delta t} \epsilon_1, x^*_{t_{M-1}} + \epsilon_x(t_{M-1}), x^*_{t_{M-1}})| \leq \hat{\epsilon}_c(1 + e^{-\Delta t}). \quad (50)
\]
The relations in (30) and Lemma 4.4 serve as the first steps in a mathematical induction proof to find an upper bound for \( \epsilon_c(t_0) \), the error in the Bermudan option price at \( t_0 \), as follows:

\[
16
\]
Theorem 4.1. For $\forall x \in [a, b], j \in \{1, \ldots, M - 1\}$, we assume that

$$
\epsilon_c(x, t_{M-j}) \leq \epsilon_c \sum_{l=1}^{j} e^{-r(l-1)\Delta t}.
$$

(51)

Then, it follows that, $\forall x$,

$$
\epsilon_c(x, t_{M-(j+1)}) \leq \epsilon_c \sum_{l=1}^{j+1} e^{-r(l-1)\Delta t}.
$$

(52)

Proof. At $t_{M-(j+1)}$, we have

$$
|\epsilon_c(x, t_{M-(j+1)})| = |\hat{c}(x, t_{M-(j+1)}) - c(x, t_{M-(j+1)})|
$$

$$
= |e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\hat{\phi}_{app}(\frac{k\pi}{b-a}; x)e^{-i\frac{k\pi n}{b-a}})(V_k(t_{M-j}) + \epsilon_V(t_{M-j}))
$$

$$
- e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\hat{\phi}_{ou}(\frac{k\pi}{b-a}; x)e^{-i\frac{k\pi n}{b-a}}V_k(t_{M-j})|
$$

$$
\leq |e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\hat{\phi}_{app}(\frac{k\pi}{b-a}; x)e^{-i\frac{k\pi n}{b-a}}\epsilon_V(t_{M-j})| + \hat{\epsilon}_c, \quad (53)
$$

where the last step follows from (29).

With arguments as in Lemma 4.3 and its proof, we have that for $\epsilon_x(t_{M-j}) > 0$, values $\delta_1 \in (x^*_{M-j} + \epsilon_x(t_{M-j}), b)$ and $\delta_2 \in (x^*_{M-j}, x^*_{M-j} + \epsilon_x(t_{M-j}))$ exist, so that,

$$
\epsilon_V(t_{M-j}) = \epsilon_c(\delta_1, t_{M-j})I_k(x^*_{M-j} + \epsilon_x(t_{M-j}), b)
$$

$$
+ (g(\delta_2, t_{M-j}) - c(\delta_2, t_{M-j}))I_k(x^*_{M-j}, x^*_{M-j} + \epsilon_x(t_{M-j})).
$$

With the induction assumptions:

$$
|\epsilon_c(\delta_1, t_{M-j})| \leq \hat{\epsilon}_c \sum_{l=1}^{j} e^{-r(l-1)\Delta t}, \quad (54)
$$

and

$$
|g(\delta_2, t_{M-j}) - c(\delta_2, t_{M-j})| \leq |\epsilon_c(x^*_{M-j} + \epsilon_x(t_{M-j}), t_{M-j})| \leq \hat{\epsilon}_c \sum_{l=1}^{j} e^{-r(l-1)\Delta t}, \quad (55)
$$

and by similar arguments as in Lemma 4.4 and its proof, we have that for
positive errors in the early–exercise point at $t_{M-j}$,

\[
|e^{-r\Delta t} \sum_{k=0}^{N-1} Re(\phi_{\text{app}}(\frac{k\pi}{b-a}; x)e^{-ik\pi\frac{a}{r}})\epsilon_V(t_{M-j})| \leq \hat{\epsilon}_c \sum_{l=1}^{j} e^{-r(l-1)\Delta t} e^{-r\Delta t} = \hat{\epsilon}_c \sum_{l=2}^{j+1} e^{-r(l-1)\Delta t}.
\]

(56)

Therefore, we find that, for $\forall x \in [a, b]$:

\[
|\epsilon_c(x, t_{M-(j+1)})| \leq \hat{\epsilon}_c \sum_{l=2}^{j+1} e^{-r(l-1)\Delta t} = \hat{\epsilon}_c \sum_{l=1}^{j+1} e^{-r(l-1)\Delta t}.
\]

(57)

\[\square\]

Remark 4.2. When $\epsilon_c(t_{M-j}) < 0$, the proof goes similarly, and we can find that $\delta_1 \in (x^*_{M-j}, b)$ and $\delta_2 \in (x^*_{M-j} + \epsilon_c(t_{M-j}), x^*_{M-j})$ exist, so that

\[
\epsilon_V(t_{M-j}) = \epsilon_c(\delta_1, t_{M-j}) I_k(x^*_{M-j}, b)
\]

\[+ (\hat{c}(\delta_2, t_{M-j}) - g(\delta_2, t_{M-j})) I_k(x^*_{M-j} + \epsilon_c(t_{M-j}), x^*_{M-j}).\]

With the induction assumptions,

\[
|\epsilon_c(\delta_1, t_{M-j})| \leq \hat{\epsilon}_c \sum_{l=1}^{j} e^{-r(l-1)\Delta t},
\]

and

\[
|\hat{c}(\delta_2, t_{M-j}) - g(\delta_2, t_{M-j})| \leq |\epsilon_c(x^*_{M-j}, t_{M-j})| \leq \hat{\epsilon}_c \sum_{l=1}^{j} e^{-r(l-1)\Delta t}
\]

we can then also prove the inequalities (56) and (57) to hold.

It follows directly from (30), Lemma 4.4 and Lemma 4.1 that at $t_0$, for any $x$, the error in the Bermudan option price satisfies:

\[
|\epsilon_c(x, t_0)| \leq \hat{\epsilon}_c \sum_{l=1}^{M} e^{-r(l-1)\Delta t} = \hat{\epsilon}_c \frac{1 - e^{-rT}}{1 - e^{-r\Delta t}} = |\epsilon_1| e^{\epsilon_\Delta t} e^{a_1} \frac{1 - e^{-rT}}{1 - e^{-r\Delta t}}.
\]

To obtain accuracy up to one basis point\(^4\) for Bermudan options, with the approximate OU process, we prescribe that for all $x$

\[|\epsilon_c(x, t_0)| < 4 \cdot 10^{-5},\]

\[^4\text{To ensure the basis point precision the error in the option price should be less than } 10^{-4}. \text{ We also consider the influence of rounding up errors, and set therefore } 4 \cdot 10^{-5} \text{ here.}\]
which is equivalent to

$$|\epsilon_1| < e^{-\kappa \Delta t} e^{-a} \frac{1 - e^{-r \Delta t}}{1 - e^{-r T}} \cdot 4 \cdot 10^{-5}. $$

Therefore, the approximate characteristic function (24) and thus the Fast Fourier Transform can be applied for pricing Bermudan options, if

$$|\epsilon_1| := |x - \mathbb{E}(x)|(1 - e^{-\kappa \Delta t}) < e^{-\kappa \Delta t} e^{-a} \frac{1 - e^{-r \Delta t}}{1 - e^{-r T}} \cdot 4 \cdot 10^{-5} =: TOL. \tag{58}$$

Finally, we need an approximation for $|\epsilon_1|$ in practice. Note that

$$0 \leq (\mathbb{E}(|x - \mathbb{E}(x)|))^2 \leq \mathbb{E}|x - \mathbb{E}(x)|^2 = \text{Var}(x) \leq \frac{\sigma^2}{2\kappa}. $$

So,

$$\mathbb{E}(|x - \mathbb{E}(x)|) \leq \frac{\sigma}{\sqrt{2\kappa}}. \tag{59}$$

In our implementation we use the upper bound of this expected value to estimate $|\epsilon_1|$ and apply the Fast Fourier Transform with the approximate characteristic function if $\frac{\sigma}{\sqrt{2\kappa}}(1 - e^{-\kappa \Delta t})$ is below the tolerance level defined by (58).

5 Numerical Results

The FFT can be applied in the parameter range for which

$$\hat{\epsilon}_1 := \frac{\sigma}{\sqrt{2\kappa}}(1 - e^{-\kappa \Delta t}) < TOL, $$

with tolerance level $TOL$ defined in (58). In the so-called “non–FFT range”, where $\hat{\epsilon}_1 > TOL$, we use the characteristic function of the original OU process to ensure accurate Bermudan option prices.

Figure 1 compares the FFT ranges with a fixed $\Delta t$, but with different maturities, $T$. With $\Delta t$ fixed, $\hat{\epsilon}_1$ remains the same for the same $\kappa$ and $\sigma$ for all maturities. However, as $T$ increases, the tolerance level (58) decreases so that we find a tighter criterion regarding the use of the FFT.

As $\sigma$ (y–axis in Figure 1) increases to certain values, we cannot employ the approximate OU model anymore, as $\hat{\epsilon}_1$ increases, resulting in a large error in the Bermudan option price.

An increase in parameter $\kappa$ (x–axis in Figure 1) also leads to a decrease of the size of the FFT range, see Figure 1, due to an increase in the value of $\hat{\epsilon}_1$ and a reduction in the tolerance level (58), see Figure 2, where $\hat{\epsilon}_1 - TOL$ is plotted as a function of $\kappa$.

Figure 3 then presents the FFT and non–FFT ranges, with $M = 5$ and $M = 50$ for $T = 1$.

As parameter $M$, the number of exercise dates, increases, the range in which the FFT can be applied expands. However, the influence of $M$ on the error and
Figure 1: FFT and non–FFT parameter ranges for different maturities, with $\Delta t = 0.1$.

Figure 2: Value of $\hat{\epsilon}_1 - TOL$ over $\kappa$, with $T = 1, M = 10, \sigma = 0.8$.

Figure 3: FFT and non–FFT parameter ranges for different numbers of early–exercise dates, with $T = 1$.

the tolerance level (58) is different for small and large model parameters. This is illustrated in Figure 4. For small $\kappa$ and $\sigma$ (example in Figure 4a), $\hat{\epsilon}_1 - TOL$ is an increasing function of $M$, whereas for large model parameters (see Figure 4b), $\hat{\epsilon}_1 - TOL$ decreases as $M$ increases.

This can be detailed by the derivative of $\hat{\epsilon}_1 - TOL$ over $M$ (in Figure 5).
In both cases, the quantity goes to zero as $M$ increases, which implies that function $\hat{\epsilon}_1 - TOL$ converges. For small parameters, $\hat{\epsilon}_1 - TOL$ converges fast, so that these sets fall in the FFT range (see Figure 3). On the other hand, as Figure 5b shows, with large model parameters, $\hat{\epsilon}_1 - TOL > 0$ when $M$ is small. For large parameter values, the approximate model can thus be used for large values of $M$. This insight is particularly helpful for parameter sets at boundary of the FFT and non–FFT ranges which will be illustrated in the next subsection.

In our next tests we randomly choose different model parameters and check whether the numerical experiments are in accordance with our error analysis. The range of parameters is $\kappa \in [0.5, 2.5]$, $\sigma \in [0.2, 0.8]$, $M \in \{5, \ldots, 20\}$, $T \in [1, 2]$, and we use seasonality function $G(t) = a_1 + a_2 \sin(a_3 t)$ with $a_1 = 3, 5, 10$, $a_2 \in [0.5, 2]$ and $a_3 \in [0.5, 2]$. Figure 6a presents results for the OU process without seasonality, whereas Figure 6b shows results for the approximate OU process with seasonality. The x–axes in the figures represent the logarithms of the error in the Bermudan option price.

In these numerical simulations we only consider the continuation values for the Bermudan options, as there is no error in the payoff function $g(x, t)$ neither in its Fourier-cosine coefficients $G_k$. For all parameter sets considered, the error
is of order $10^{-4}$ or less, which implies that our approximation is accurate up to one basis point.

5.1 CPU Time and Accuracy

We perform some more experiments checking the validity of the error analysis.

We first consider the OU process without seasonality and choose the following four sets of model parameters for the numerical examples and set $T = 1$ and $M = 10, 20, 50$:

1. $\kappa = 0.301, \sigma = 0.334$. This parameter set originates from commodity price calibration in [10].

2. $\kappa = 1, \sigma = 0.5$. This parameter set lies “in the FFT range” for $M = 10, 20, 50$, as in Figure 3.

3. $\kappa = 2, \sigma = 0.7$. This parameter set is at the boundary of the FFT range (but still inside the FFT range) for $M = 10, 20, 50$, see Figure 3.

4. $\kappa = 2.5, \sigma = 1$. This parameter set lies outside the FFT parameter range for $M = 10, 20, 50$, see Figure 3.

For each parameter set, the CPU time, in seconds, as well as the error are recorded. We set $N = 512$ for which we are sure that convergence is achieved in space when $M = 20$ and $M = 50$.

The numerical results are listed in Table 1, where \textit{CPU time 1} and \textit{CPU time 2} are the run-times of the Bermudan COS method with the original and the approximate OU model, respectively. Moreover, the $\log_{10}(\text{error})$ quantity in the table represents the logarithm of the absolute error in the Bermudan option price from the approximate model.

\footnote{The FFT is used with the approximate OU model.}

 & CPU time 2 & 0.0287 & 0.0296 & 0.0301 & 0.0300 \\
\hline
\end{tabular}
\caption{CPU time and error for the two OU processes and different model parameters.}
\end{table}

In Table 1 it is shown that for all parameter sets in the FFT range (sets 1 to 3), we can confirm the basis point precision. Moreover, the CPU time drops from seconds to milli–seconds if the FFT can be applied. As $\kappa$ and $\sigma$ increase (from sets 1 to 4), the error increases and the size of the FFT range reduces. This agrees with our analysis. For parameter set 4, for instance, only the use of the original characteristic function ensures the basis point precision.

5.1.1 Probability Density Function of $\epsilon_1$

In this subsection we take a closer look at the error in the characteristic function, $\epsilon_1$:

\[ \phi_{app}(u, x) = \phi_{ou}(u, x)e^{iux}. \]  

(60)

We have already seen that $\epsilon_1 := (x - \mathbb{E}(x))(1 - e^{-\kappa\Delta t})$. It is a normally distributed process, with $\mathbb{E}(\epsilon_1) = 0$ and $\text{Var}(\epsilon_1) = \frac{\sigma^2}{2\kappa}(1 - e^{-2\kappa t})(1 - e^{-\kappa\Delta t})$, because the OU process is also normally distributed.

Larger values of parameter $t$ will give rise to larger variance in $\epsilon_1$, with fixed value for $\Delta t$. Therefore we analyze here the error $\epsilon_1$ at time point $T - \Delta t$, which gives us the largest variance in the backward recursion. The probability density functions for $\epsilon_1$ with $T = 1$ and $T = 2$ are shown in Figures 7 and 8, respectively. We have chosen the parameter sets used earlier, i.e., parameter set 1 with $\kappa = 0.301$ and $\sigma = 0.334$ (well in the FFT range) and set 3 with $\kappa = 2$ and $\sigma = 0.7$ (at the boundary of the FFT range) with $T = 1$. For $T = 2$ we used $\sigma = 0.4$ in set 3, so that this set also falls in the FFT range for this test.

For the OU processes with and without seasonality, when model parameters are fixed, the density function of $\epsilon_1$ is essentially the same (with the same variance).

From these figures we see that with $T$ fixed, larger values for $M$ result in smaller errors in $\epsilon_1$. Moreover, small values for $\kappa$ and $\sigma$ also bring smaller errors in characteristic function, compared to the larger model parameters.
5.1.2 Early-Exercise Points

In this subsection we compare the early–exercise points obtained from the original and approximate characteristic functions, $\phi_{\text{org}}(u, x)$ and $\phi_{\text{app}}(u, x)$, respectively. We present early–exercise point $x^*_T=\Delta t$, i.e. the value at the last time step of the backward recursion, with $T = 1$ and $M = 10, 20, 50$.

We use here parameter set 1 ($\kappa = 0.301, \sigma = 0.334$) and parameter set 3 ($\kappa = 2, \sigma = 0.7$, at the boundary of the FFT parameter range).

The results are shown in Table 2.

In Table 2 we see an increasing error in the early–exercise point, especially for parameters near the boundary of the range of $\kappa$- and $\sigma$-values for which the FFT can still be applied. With small parameter values for $\kappa$ and $\sigma$, the error is relatively small (0.08 in Table 2).

Obviously, the Bermudan option prices with the approximate process are much more accurate than the values of the corresponding early-exercise points.
Table 2: Early–exercise points at $t = \Delta t$ for Bermudan put options; parameter sets 1 and 3, $T = 1$, different values for $M$ (no seasonality).

This can be understood from Equation (37) in our error analysis. There the error in the continuation value is divided by a small number (as $f'(x, t)$ is defined as the derivative of the difference of the continuation value and the payoff), resulting in a bigger error in $\epsilon_x$, which is the error in the early-exercise points.

5.1.3 Seasonality Experiment

Now we end with some test cases with seasonality. Our aim is to show that the approximation works well for different seasonality functions. Two seasonality functions are used:

1. Seasonality Function 1: $G(t) = 5 + \sin(t)$,
2. Seasonality Function 2: $G(t) = 3 + 4 \cos(0.25t)$.

We check two parameter sets at the boundary of the FFT range, see Figure 1 and Figure 3.

1. Parameter Set 1: $\kappa = 1.5, \sigma = 0.8, T = 1$.
2. Parameter Set 2: $\kappa = 0.85, \sigma = 0.7, T = 2$.

CPU time as well as the log–absolute error in the option price from our approximate model for different $M$ are presented in Table 3. For these parameter sets at boundary, we cannot achieve basis point precision for small values of $M$. However, the error drops below the tolerance level as $M$ increases, which is in accordance with our analysis.

6 Conclusion

In this paper, we derive a characteristic function for an approximation of the well-known OU process. This approximation enables us to apply the Fast Fourier Transform when pricing Bermudan options by means of the COS method. The approximate process may be employed if the error generated by the approximation is less than a prescribed tolerance level. We would like to ensure that the Bermudan option prices are accurate up to a basis point. This tolerance
level is determined by a detailed error analysis. In various numerical experiments it is demonstrated that the characteristic function for the approximate process, in combination with the tolerance level, predicts well for which model parameter ranges, numbers of early-exercise dates and seasonality functions the FFT can be safely applied. For the model parameter sets for which the error is below the tolerance level and our approximation can thus be applied, we have reduced the computational time for pricing of Bermudan options under the OU process from seconds to milliseconds.
